# DISCUSSION

- Western Uganda, especially the Rwenzori Mountains, emerged as the core high-suitability zone across all species. Recognized as a major African center of plant endemism and elevational microclimatic diversity (Burgess et al., 2007).
- *Warburgia ugandensis* & *Prunus africana*: High suitability concentrated in humid, high-altitude forests.
- *Maesa lanceolata*: Broader moderate suitability across central, eastern, and parts of northern Uganda; persistence in secondary forests and forest edges reflects ecological flexibility (Friis et al., 2010).
- *Albizia coriaria* & *Albizia gummifera*: Wider suitability including agroforestry and disturbed landscapes; optimal conditions remain in wetter western and central Uganda (Orwa et al., 2009).
- *Arundinaria alpina*: Strong confinement to western highlands (>2,000 m a.s.l.); sharp decline toward lowlands highlights vulnerability to climate warming and land-use change (Kigomo, 1988).

# CONCLUSION

- The results revealed clear spatial variation in habitat suitability across Uganda, with highly suitable areas mainly concentrated in the western and south-western highlands, particularly within and around RMNP.
- Findings show that altitude, climate, soil characteristics, and land use strongly influence species distribution.
- The study also identified suitable areas outside the park that could support ex-situ conservation, helping to reduce pressure on in-situ populations while maintaining community access to plant resources.
- Generally, the research demonstrates that land suitability mapping is an effective decision-support tool for conservation planning, restoration, and sustainable plant resource management in the Albertine Rift region.

# RECOMMENDATIONS

- Promote ex-situ conservation: Uganda Wildlife Authority and National Forestry Authority should establish botanical gardens, community nurseries, and enrichment planting programs targeting highly exploited species such as *Prunus africana* and *Warburgia ugandensis*.
- Integrate suitability maps into planning: Incorporate generated land suitability maps into Rwenzori Mountains National Park management plans to guide restoration, buffer zone management, and species-specific conservation actions.
- Support community cultivation: Provide seedlings, technical training, and market linkages to communities around RMNP to reduce illegal harvesting and enhance household incomes.
- Strengthen enforcement & monitoring: Use identified suitability hotspots within RMNP to prioritize patrols, monitoring, and ecological restoration efforts.
- Enhance adaptive management: Regularly update land suitability models to reflect climate change and land-use dynamics; expand future research to include more threatened species and socio-economic drivers.
